Abstract
The Kuala Lumpur City Hall (KLCH) has planted 100,000 trees along the main streets of the city centre through the National Economic Transformation Programme to make the city more liveable. This paper studies the reasons for its different establishments and determines its social and physical benefits to the pedestrian walkways through a further investigation regarding the morphological parameters used by the Landscape Department of KLCH. The outcomes indicated that the street vegetation morphology implemented is mainly to improve the social and physical condition of the pedestrian walkways especially the safety of the pedestrians due to snatching and reckless crossings.

Keywords: Street Vegetation; City Centre; Main Street; Pedestrian Walkways

1.0 Introduction
Street vegetation has been an integral part of the urban landscape. It was the Italian Renaissance and French Baroque influence that introduced the concept of planting rows and avenues of trees (Chevallerie, 1983). Trees were often believed to serve the environment like air and water purifier, wind and noise filter, which, are crucial significance for the liveability of modern cities and the well-being of urban residents (Chiesura, 2004). The earliest urban tree planting in Malaysia was recorded more than a century ago. Angsana (Pterocarpus indicus) was reported to have been planted in 1778 in Malacca (Koenig, 1894) and Penang in 1802 (Burkill, 1966).

The very first planned greening programme in Malaysia started in the Federal Territory of Kuala Lumpur was in 1973 under the Beautification Programs of Kuala Lumpur (Ayoub, 1989) and greening the city program in Kuala Lumpur was officially instituted in the planning process when the 1973 Act 267 was revised in the Federal Territory (Planning) Act of 1982 (Act 267). It stipulated the rules and regulations for planting, cutting, and conservation of urban trees. Other than the tree planting program, an emphasis on urban tree planting has also been included in the Kuala Lumpur Structure Plan (DBKL, 2004). This includes the planting of shade trees, the establishment of themed gardens, beautification and ornamental plantings, slope planting, roadside planting and beautification and ground cover (Sreetheran, 2011).
With the Kuala Lumpur city centre rail transports completely opened in 1999, its main rapid-city centre interchange station at Masjid Jamek, the pedestrian network around its immediate context was developed. Connecting main transport nodes required widening and shading of walkways with a more attractive appearance to provide a pleasant walking experience. The Economic Transformation Program (ETP) in September 2010 was initiated to elevate the country to developed-nation status by 2020. As part of the efforts, KLCH aimed to increase greenery in the city by planting 100,000 large-coverage trees within three years from 2011 to 2014. Considering these circumstances, a greater understanding of the physical properties, the components, and elements possessed by the street vegetation as part of improved pedestrian walkway design are hoped to be discovered. This study aims to explore the development of the street vegetation of the three year-tree planting projects and review its establishments along the pedestrian network of the main roads in the city centre. The review is only part of determining the process to explore how street vegetation is established within the city hall’s morphological parameter and its contribution to safe and pleasant walking experience for pedestrians.

2.0 Literature Review
Morphology is defined as the study of forms of things and the shape of a structure. It is the branch of biology that deals with the form of living organisms, and with relationships between their structures (Oxford, 2012). Morphology of vegetation comprises of structural properties of vegetation, mainly in the height, density, species, and functionality along with its composition (Mishra, 2015). Vegetation morphology, on the other hand, is usually developed based on physiognomy (i.e., structure and density) and species composition. It is usually the accurate representation of the typical co-existence of trees, shrubs, and grasses considering the layering system of vegetation and vegetation properties.

2.1 Historical background of street trees
The earliest features of rows of trees along a street date back nearly 500 years from the present day. Tree-lined avenues made its first appearance on the European continent in the Italian Renaissance gardens of the first half of the 16th century. They were then “imported” to France which had been used for passageways in buildings and now came to designate a passageway in most gardens (Pradines, 2009). During the Renaissance, trees were in private gardens for fruit production and aesthetics. Renaissance villas were walled with gardens and trees were lined as pathways in the gardens (Miller, 2014).

In the beginning, the rows of trees were only to create a focal point in the gardens, but designers soon had the idea of creating vistas, which led into the distance towards the summit of a nearby mountain or a far-off castle, therefore, creating tree-lined roads. Within towns and cities, the appearance of tree-lined streets was driven by other changes. From the early of the 19th century, cities like St. Petersburg and cities in Scandinavia like Helsinki and Vanersborg in Sweden started to create wide thoroughfares that were planted with trees. It was to prevent and limit the destruction caused by fires. The planting of trees along roadways was also influenced by the desire to prevent neighbouring landowners trespassing on public territory and vice versa. It also fulfilled a technical function: trees drained and stabilised the highway verges. Trees along the street were also known to shelter travelers from the wind, provide shade in sunny areas and prevent soil erosion caused by wind.

2.2 Rationale of implementation of urban vegetation along streets
In the cities, trees are commonly planted to provide shade and refresh the environment by evapotranspiration (Dimoudi, 2003). Physically, trees are planted in urban areas to improve the appearance of the streets. Kent (1983) demonstrated the positive effects of naturalistic roadways where there is a greater appreciation of freeway roadides with trees. The roadside environment also influences road choice. Research by Smardon (1988) concluded that all forms of vegetation contribute to visual improvement where trees break up continuous building facades and provide delineation of space, shrubs anchor structures to the ground and grass and ground cover help to define pavement edges.

2.3 Impact of urban vegetation on the streets and pedestrian walkways of cities
Most city-dwellers spend their time on the streets. Some streets are not at all attractive to pedestrians and drivers whereas some may be equally appealing to both users. According to Jacobs (1997), streets should be comfortable and appealing with places to walk at a leisurely pace in safety and have something to catch the eyes of both pedestrians and drivers. Included, in the list qualities that great street should include is vegetation (Antiput, et al., 1996). It has been shown that the presence of trees is vital and valuable for the urban environment of a streetscape (Anderson1988).

2.4 Impact of pedestrian walkways
The presence of trees encourages people to walk as an exercise and as a mode of transportation (Mitchell, 2007). When trees are planted along the curb, especially when closely spaced, it helps define a pedestrian zone separated from traffic, which creates a sense of safety both physically and psychologically (Foundation, 2003). Safety perception of users is an important component of walkability and there is a high safety aspect when trees are planted in between footpath and roadway which also reduces the risk of being hit by a ‘run-off-the-road’ vehicle (Jacobs, 1993). Trees are also proven to reduce the temperatures of the surfaces they shade up to 25°C (Walks, 2017). It is critical to include trees and landscaping in the street environment so that people would want to walk in, especially as a mode of transportation in the city centre.
Furthermore, Walks (2017) added that benefits for walkers comprise both practical and aesthetic with street trees providing shelter for the pedestrian walkways.

2.5 Impact of urban vegetation in the city
Street trees are of a significant component of the wider urban forest. These components are referred to as a city’s green infrastructure. The concept of green infrastructure is derived from the awareness that the natural system can perform a range of engineering, environmental and human functions. It can deliver multiple benefits from the urban space it occupies as compared to a single purpose engineering infrastructure in the city (Foundation, 2003). A city must have a strong connecting green asset. Urban vegetation is a critical contributor to the great streetscape and good walkability. Good streets and walkability are essential for a sustainable city (Zakaria, 2015).

A study has also established by Technology (2012) that trees, shrubs and other greenery growing in the concrete-and-glass canyons of cities can reduce levels of the two most worrisome air pollutants by eight times more than previously believed, making a city more liveable and healthy. Therefore, urban vegetation does give a huge impact on the quality of a city as it improves the walkability of the streets, which improves the residents’ quality of living and promotes a more sustainable environment thus creating a liveable place that enhances the quality of access and linkages in neighbourhoods, town centre and urban areas (Shamsuddin, 2012).

3.0 Methodology
This study employed a qualitative method at the selected areas of the selected main streets, which are directly linked to the main street of the Masjid Jamek LRT interchange station, Jalan Tun Perak (Figure 1). Eight main streets found to have this criterion including Jalan Tun Perak itself, which has undergone the greening works by the city hall from the ETP initiated by the government. The greening works took place from the end of the year 2012 until the end of the year 2015.

(Source: Author)

The objective of this study is to explore the morphology of street vegetation along the main streets of the city centre and to discover the list of street vegetation design components constructed by the KLCH. This research is done via observation and archiving of the components of street vegetation in detail. This data record would then make clear evidence of the existing street vegetation works done by the city hall’s landscape architects, which discovers its reasons for the establishment; street vegetation morphological parameter set by the city hall, its objectives, and relation to the pedestrian walkway of the city centre. Due to time limitation, this study only covers the main streets that were involved in the ETP and its relation to the pedestrian walkways.

4.0 Findings
Street Vegetation Morphology Components
Based on the components of vegetation morphology studied in the literature review, vegetation morphology is usually developed based on vegetation physiognomy; structure and density (Mishra, 2015). From this, the elements that are being measured are the dimensions of the tree canopy, shrubs, pedestrian walkways, and other structures, which are built together with the street vegetation like street lamps, fences or seating furniture. Interview done with the landscape architect of the KLCH will help to understand the effects and rationale of the recorded observation and dimensions through the aspects of i) Street Location, ii) Safety, iii) Comfort and iv) Visual Aesthetics.

3
4.1 Street Location
Based on the interview with the Deputy Director of Landscape and Recreational Department of KLCH, Nik Adlin Nik Hussain, there are different parameters set by the city hall for the establishment of the green zone following the Greener KL project set by PEMANDU. Being given the responsibility to plant 100,000 trees within three years, the street vegetation is planted mainly according to the location of the streets. Nik Adlin mentioned, “The trees are usually chosen based on the site constraints. For example, hardy plants are plants that require low maintenance like watering. Even without regular watering, these plants should be able to grow on their own. The important site which is nearer to the protocol area like Jalan Raja, where the Merdeka Square is, has more labour supplies since the city hall is being given more budgets to cater to the plants. The vegetation planted on such site is also composed of more expensive plants”.

Therefore, streets like Jalan Raja Chulan and Jalan Ampang are planted with more hardy plants since they are located further down from Masjid Jamek LRT station and do not carry any protocol requirement as compared to other streets, which have important buildings around them.

4.2 Safety
Nik Adlin cited that Kuala Lumpur started to plant more trees as a barrier and edging to separate the road and the pedestrian walkway since the Safe City Campaign took place in the year 2010 (Government, 2010). When trees are planted along a curb, it helps define the pedestrian zone separated from the traffic which creates a sense of safety both physically and psychologically (Foundation, 2003). He added, “We can’t compare the reasons for the establishment of street vegetation in Kuala Lumpur and other countries. Here, we plant trees and shrubs for very different reasons due to local behaviour and culture. Most developed countries do not have barricade or fencing along the street vegetation, but Kuala Lumpur needs it due to many cases of road accidents, snatching and illegal usage of pedestrian roads by motorcyclists”.

When trees are planted in between footpath and roadway, the risk of being hit by a run-off-the-road vehicle is reduced (Jacobs, 1990). In Kuala Lumpur, trees and shrubs are planted to prevent vehicles from hitting a person first. Instead, with this strategy, it is more likely for the vehicles to hit the green zone first, either tree or the shrubs.

4.3 Comfort
Being given the trust by the ministry for the Greener KL project, the Landscape and Recreational Department of the City Council of Kuala Lumpur also intended for the vegetation planting to improve the walking environment of the pedestrians in the city centre. It is said to be critical to include trees and landscaping in the street to create an environment that people would want to walk in. The practical benefit is when the trees provide shelter for pedestrian walkways (Walks, 2017). As explained by Nik Adlin, “The areas where the trees and shrubs are planted along the pedestrian walkways are recognised as the ‘green zone’ where this zone intends to enhance the surrounding requirements. They are established to connect the existing pedestrian walkways where walking feels easier and more comfortable for the pedestrians to reach one place to another”.

Urban vegetation gives a huge impact on the quality of a city. As it improves the walkability of the streets, it creates a liveable place. A liveable place enhances the quality of access and linkages in the town centre and urban areas and a city become liveable when transportation is made sustainable with low noise and air pollution which will then contribute to a comfortable walk.

4.4 Visual Aesthetics
Nik Adlin stated, “The green zones are usually in line with all the utilities like the street lamps, electrical poles, etc. This is for easy reference and also for a clean arrangement for the street. We have also designed the green zone, especially in Jalan Tuanku Abdul Rahman (TAR), with all the design elements of colours, texture, and line which compose a form. All these elements are to add up to the beautiful characteristics of Jalan TAR itself. Since it is a place for tourists and local shopping areas, we have given Jalan TAR a specific theme. A colourful, merrier looking landscape”.

It was concurred by Smardon (1988) that all forms of vegetation contribute to visual improvement where trees break up continuous facades and provide delineation of space, shrubs anchor structures to the ground and grass and ground cover help to define pavement edges.

6.0 Conclusion & Recommendations

The findings suggest that the reason for the establishment of the street vegetation to the pedestrian walkway along the main streets of Kuala Lumpur city centre is mainly responding to the safety of the pedestrians. The negative culture of snatching and reckless crossing among the locals requires street vegetation to form a clear division separating the pedestrian and street zones. Landscape works of vegetation planting help to separate the pedestrians from the vehicles on the road and keep motorcyclists out. The presence of trees also encourages people to walk (Mitchell, 2007). Therefore, more people are walking, natural surveillance is increased and prevents thefts like snatching.

Street vegetation along these streets also aims to prevent pedestrians from reckless crossings as they are planted continuously along the streets. Pedestrians are indirectly forced to cross only when there are green zone breaks and from this study, it is shown that most landscape breaks are in the same location as the pedestrian crossings.

Before the implementation of the street vegetation through the number six of the Entry Point Projects (EPPs) to greening Greater Kuala Lumpur, the selected main streets did not have any trees along the pedestrian walkways which made it very uncomfortable to walk on. Even though many streets from this study showed that most of the trees planted did not give enough canopy to the pedestrian walkways, the walkways seem much better with the planted trees and shrubs. The element of softscape which has been added to the streetscape does give more comfort to the pedestrian. A study by Technology (2012) stated that shrubs and other greenery growing in the concrete-and-glass canyons of cities can reduce levels of the two most worrisome air pollutants by eight times more thus making it more comfortable to walk.

Street vegetation planting is established to introduce an inviting walking environment. Trees and landscaping along the streets create a friendlier environment for people to walk (Walks, 2017). Since the selected main streets in this study are directly linked to Jalan Tun Perak where Masjid Jamek LRT transit station is located, the city hall must introduce the green zones along these streets. Data collection of pedestrian movement and distribution around the main transit hub of Kuala Lumpur would contribute to better landscape planning. The city hall shall utilise this information to plant more specific, responsive, and effective types of trees and shrubs that would protect and comfort pedestrians.

Acknowledgment

Thank you to Landscape Architect Nik Adlin Nik Hussain, Head of Landscape Department of Kuala Lumpur City Hall and the Department of Architecture, Faculty of Built Environment, the University of Malaya for their support in this research.
